bounded Baire group

Baire subgroups of \mathbb{T}

\mathbb{T} is the subgroup of the multiplicative group $\mathbb{C} \setminus \{0\}$ formed by all complex numbers with modulus 1, and endowed with the usual topology.

We consider on \mathbb{T} the arc-length group norm ρ , normalized in such a way that $\rho(-1) = 1/2$. For every $\varepsilon > 0$ we denote by T_ε the neighborhood of 1 defined by $\{t \in \mathbb{T} : \rho(t) < \varepsilon\}$.

If G is an abelian group, we call any element of $\text{Hom}(G, \mathbb{T})$ a *character* of G .

Let (G, τ) be a Hausdorff *topological* abelian group. We denote by $(G, \tau)^\wedge$ the subgroup of $\text{Hom}(G, \mathbb{T})$ formed by all τ -continuous characters of G . We say that (G, τ) is MAP if the elements of $(G, \tau)^\wedge$ separate the points of G .

the Baire property

Compact subsets of a
precompact,
bounded Baire group

Baire subgroups of \mathbb{T}

We say that (G, τ) is *precompact* if G can be covered by finitely many translates of any neighborhood of zero. Equivalently, if the completion $\varrho(G, \tau)$ of (G, τ) is a compact group.

We say that (G, τ) is *pseudocompact* if every τ -continuous real function defined on G is bounded. Equivalently, if (G, τ) is precompact and G_δ -dense in its completion.

Some notations and preliminary facts

The Baire property
on precompact
abelian groups

A *duality* of the abelian groups G and H is defined by a bihomomorphism $\langle \cdot, \cdot \rangle : G \times H \rightarrow \mathbb{T}$. We will consider *separated* dualities: for every $g \in G \setminus \{0\}$ and every $h \in H \setminus \{0\}$ the characters $\langle g, \cdot \rangle$ and $\langle \cdot, h \rangle$ are not identically 1.

Given any duality $\langle G, H \rangle$ the inverse duality $\langle H, G \rangle$ is defined in the obvious way.

We denote by $\sigma(G, H)$ the initial topology on G with respect to all characters of the form $\langle \cdot, h \rangle$ where $h \in H$.

A basis of neighborhoods of 0 for $\sigma(G, H)$ is given by the sets $\{g \in G : \langle g, \Delta \rangle \subset T_\varepsilon\}$ where Δ runs over all finite subsets of H and $\varepsilon > 0$.

$\sigma(G, H)$ is a Hausdorff, precompact group topology, and $(G, \sigma(G, H))^\wedge = H$ in the natural way.

Baire subgroups of \mathbb{T}

If (G, τ) is MAP, there is a natural duality $\langle G, (G, \tau)^\wedge \rangle$. It turns out that (G, τ) is precompact if and only if $\tau = \sigma(G, (G, \tau)^\wedge)$.

Similarly, $\sigma((G, \tau)^\wedge, G)$ is the topology on $(G, \tau)^\wedge$ of pointwise convergence on the elements of G .

the Baire property

Compact subsets of a
precompact,
bounded Baire group

Baire subgroups of \mathbb{T}

The duality $\langle G, H \rangle$ is *bounded* if for some $m \in \mathbb{N}$ we have $mG = \{0\}$, equivalently $mH = \{0\}$.

If $\langle G, H \rangle$ is bounded, a basis of neighborhoods of 0 for $\sigma(G, H)$ is given by the *subgroups*
 $\{g \in G : \langle g, \Delta \rangle = \{1\}\} =: \Delta^\perp$ where Δ runs over all
finite subsets of H .

A topological space X has the Baire property, or is a Baire space, if the intersection of any countable family of open dense subsets of X is dense in X .

Equivalently, if the only open subset in X which is expressible as a countable union of nowhere dense subsets of X is the empty set.

Every locally compact space has the Baire property.

Every completely metrizable space has the Baire property.

precompact,
bounded Baire group

Baire subgroups of \mathbb{T}

The Baire property plays a role in

- the open mapping/closed graph theorems
- joint continuity of bi-homomorphisms
- Klee's theorem on complete metrics
- Mackey-type properties for topological abelian groups
- ...

Some known facts on precompact, Baire groups

The Baire property
on precompact
abelian groups

Introduction

A characterization of
the Baire property

Compact subsets of a
precompact,
bounded Baire group

Baire subgroups of \mathbb{T}

- Every pseudocompact group is a Baire space.
- If G is infinite abelian, then $(G, \sigma(G, \text{Hom}(G, \mathbb{T})))$ is *not* a Baire space.
- The class of precompact Baire groups is closed with respect to taking continuous homomorphic images and arbitrary direct products (M. Bruguera, M. Tkachenko, 2012).
- If the precompact group $(G, \sigma(G, H))$ is Baire, all convergent sequences in $(H, \sigma(H, G))$ are stationary (same reference).

A characterization of the Baire property

The Baire property
on precompact
abelian groups

Introduction

A characterization of
the Baire property

Compact subsets of a
precompact,
bounded Baire group

Baire subgroups of \mathbb{T}

Let $\langle G, H \rangle$ be a bounded duality of abelian groups. Fix $g \in G$ and a finite subset Δ of H . The set $g + \Delta^\perp$ is an open $\sigma(G, H)$ -neighborhood of g . (It is the set of all $g' \in G$ which agree with g on Δ .)

Fix a sequence $\{g_n\}$ in G and a sequence $\{\Delta_n\}$ of finite subsets of H . Consider the sets $\bigcup_{k \geq n} g_k + \Delta_k^\perp$, where $n \in \mathbb{N}$. They are clearly $\sigma(G, H)$ -open.

Moreover they are $\sigma(G, H)$ -dense in G if $\langle \Delta_n \rangle \cap \langle \Delta_k \rangle = \{0\}$ whenever $n \neq k$.
(We will check this later.)

So, if $(G, \sigma(G, H))$ is a Baire group, then

$\bigcap_{n \in \mathbb{N}} \bigcup_{k \geq n} g_k + \Delta_k^\perp$ is nonempty: there is some g such that $g \in g_k + \Delta_k^\perp$ for *infinitely many* $k \in \mathbb{N}$.

precompact,
bounded Baire group

Baire subgroups of \mathbb{T}

Let $\langle G, H \rangle$ be a bounded duality of abelian groups.

If $(G, \sigma(G, H))$ is a Baire group, then

for every sequence $\{g_n\}$ in G and every sequence $\{\Delta_n\}$ of finite subsets of H with $\langle \Delta_n \rangle \cap \langle \Delta_k \rangle = \{0\}$ whenever $n \neq k$, there is $g \in G$ such that $g \in g_n + \Delta_n^\perp$ for *infinitely many* $n \in \mathbb{N}$. (That is, g agrees with g_n on Δ_n for infinitely many n .)

This necessary condition is actually also sufficient!

A characterization of the Baire property

 $(G, \sigma(G, H))$ is a Baire group if and only if
for every sequence $\{g_n\}$ in G and every sequence $\{\Delta_n\}$ of
finite subsets of H with $\langle \Delta_n \rangle \cap \langle \Delta_k \rangle = \{0\}$ whenever
 $n \neq k$, there is $g \in G$ such that $g \in g_n + \Delta_n^\perp$ for *infinitely*
many $n \in \mathbb{N}$. (That is, g agrees with g_n on Δ_n for infinitely
many n .)

A characterization of the Baire property

The Baire property
on precompact
abelian groups

Introduction

A characterization of
the Baire property

Compact subsets of a
precompact,
bounded Baire group

Baire subgroups of \mathbb{T}

Let $\langle G, H \rangle$ be a bounded duality of abelian groups. Let $\{g_n\}$ be a sequence in G and $\{\Delta_n\}$ a sequence of finite subsets of H with $\langle \Delta_n \rangle \cap \langle \Delta_k \rangle = \{0\}$ whenever $n \neq k$. Then for every $n \in \mathbb{N}$ the set $\bigcup_{k \geq n} g_k + \Delta_k^\perp$ is $\sigma(G, H)$ -dense in G .

Proof: Fix $n \in \mathbb{N}$ and a basic $\sigma(G, H)$ -open set $g_0 + \Delta_0^\perp$ in G . We need to find some

$g \in (g_0 + \Delta_0^\perp) \cap (\bigcup_{k \geq n} g_k + \Delta_k^\perp)$. This means

$\langle g, h \rangle = \langle g_0, h \rangle$ for every $h \in \Delta_0$

$\langle g, h \rangle = \langle g_k, h \rangle$ for every $h \in \Delta_k$ (we can choose $k \geq n$.)

Pick $k \geq n$ so that $\langle \Delta_0 \rangle \cap \langle \Delta_k \rangle = \{0\}$. Consider the character on $\langle \Delta_0 \rangle \oplus \langle \Delta_k \rangle$ acting as $\langle g_0, \cdot \rangle$ on Δ_0 and as $\langle g_k, \cdot \rangle$ on Δ_k . Since $\langle \Delta_0 \rangle \oplus \langle \Delta_k \rangle$ is finite, this character can be extended to a continuous character of the precompact group $(H, \sigma(H, G))$, that is, to some element of G as required.

By using similar techniques one can prove that

- Let $\langle G, H \rangle$ be a bounded duality of abelian groups. Suppose that $(G, \sigma(G, H))$ is a Baire space. Then every $\sigma(H, G)$ –compact subset of H is finite.

This was known for pseudocompact (not necessarily bounded) groups.

It is not true with “countably compact” instead of “compact”, even in the Boolean case.

Baire subgroups of \mathbb{T}

Let $\langle G, H \rangle$ be a bounded duality of abelian groups.
Suppose that $(G, \sigma(G, H))$ is a Baire space. Then every
 $\sigma(H, G)$ –compact subset of H is finite.

Some consequences:

- If G is a bounded, precompact abelian group which is a Baire space, then its topology is the only locally quasi-convex one with its group of continuous characters.
- If G is a bounded, precompact abelian group which is a Baire space and has only finite compact subsets then G is reflexive.

Introduction

A characterization of
the Baire property

Compact subsets of a
precompact,
bounded Baire group

Baire subgroups of \mathbb{T}

Let S be a dense subgroup of \mathbb{T} . Then S has the Baire property iff for every $(\varepsilon_k) \in (0, \infty)^{\mathbb{N}}$, every $(t_k) \in \mathbb{T}^{\mathbb{N}}$ and every faithfully indexed $(m_k) \in \mathbb{Z}^{\mathbb{N}}$ there is some $t \in S$ with $t^{m_k} \in t_k T_{\varepsilon_k}$ for infinitely many k .

Sketch of the proof of \Leftarrow : Fix a decreasing sequence (U_n) of open, dense subsets of \mathbb{T} ; let us show that $\bigcap_n U_n \cap S \neq \emptyset$. Any open, dense subset of \mathbb{T} contains the set of all k th roots of a convenient basic neighborhood tT_{ε} . Find t_k, ε_k ($k \in \mathbb{N}$) with $u^k \in t_k T_{\varepsilon_k} \Rightarrow u \in U_k$. Apply our hypothesis with $m_k = k$: we find $t \in S$ with $t^k \in t_k T_{\varepsilon_k}$ for infinitely many k . We deduce that $t \in U_k$ for infinitely many k , thus actually for all k .

Baire subgroups of \mathbb{T}

Compact subsets of a
precompact,
bounded Baire group

Baire subgroups of \mathbb{T}

*Let $\langle G, H \rangle$ be a bounded duality of abelian groups.
 $(G, \sigma(G, H))$ is a Baire group if and only if for every
sequence $\{g_n\}$ in G and every sequence $\{\Delta_n\}$ of finite
subsets of H with $\langle \Delta_n \rangle \cap \langle \Delta_k \rangle = \{0\}$ whenever $n \neq k$,
there is $g \in G$ such that g agrees with g_k on Δ_k for
infinitely many k .*

Note that the topology on S is exactly $\sigma(S, \mathbb{Z})$.

[S is precompact, hence its topology is $\sigma(S, S^\wedge)$. But
 $S^\wedge = \mathbb{T}^\wedge = \mathbb{Z}$.]

We have just seen that

$S = (S, \sigma(S, \mathbb{Z}))$ is a Baire group iff for every sequence
 (t_n) in \mathbb{T} and every faithfully indexed sequence $\{m_n\}$ in \mathbb{Z}
there exists some $t \in S$ such that t “almost agrees” with t_n
on $\{m_n\}$ for infinitely many n .
